### SAST Scan Results (947)

#### Stored\_XSS (Type)

Query Path: PHP/PHP\_Critical\_Risk/Stored\_XSS

CWE Id: 79

Total results: 51

Description: The method @DestinationMethod embeds untrusted data in generated output with @DestinationElement, at line @DestinationLine of @DestinationFile. This untrusted data is embedded into the output without proper sanitization or encoding, enabling an attacker to inject malicious code into the generated web-page. The attacker would be able to alter the returned web page by saving malicious data in a data-store ahead of time. The attacker's modified data is then read from the database by the @SourceMethod method with @SourceElement, at line @SourceLine of @SourceFile. This untrusted data then flows through the code straight to the output web page, without sanitization. This can enable a Stored Cross-Site Scripting (XSS) attack.

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002490 - CAT I The application must protect from Cross-Site Scripting (XSS) vulnerabilities.
- CWE top 25: CWE top 25
- FISMA 2014: System And Information Integrity
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Verification and representation of input data
- NIST SP 800-53: SI-15 Information Output Filtering (P0)
- OWASP ASVS: V05 Validation, Sanitization and Encoding
- OWASP Top 10 2013: A3-Cross-Site Scripting (XSS)
- OWASP Top 10 2021: A3-Injection
- PCI DSS v3.2.1: PCI DSS (3.2.1) - 6.5.7 - Cross-site scripting (XSS)
- PCI DSS v4.0: PCI DSS (4.0) - 6.2.4 Vulnerabilities in software development
- SANS top 25: SANS top 25
- Top Tier: Top Tier

## Second\_Order\_SQL\_Injection (Type)

Query Path: PHP/PHP\_Critical\_Risk/Second\_Order\_SQL\_Injection

CWE Id: 89

Total results: 71

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets database data from the @SourceElement element. This element's value then flows through the code without being properly sanitized or validated, and is eventually used in a database query in method @DestinationMethod at line @DestinationLine of @DestinationFile. This may enable an Second-Order SQL Injection attack.

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002540 - CAT I The application must not be vulnerable to SQL Injection.
- CWE top 25: CWE top 25
- FISMA 2014: System And Information Integrity
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Verification and representation of input data
- NIST SP 800-53: SI-10 Information Input Validation (P1)
- OWASP ASVS: V05 Validation, Sanitization and Encoding
- OWASP Top 10 2013: A1-Injection
- OWASP Top 10 2021: A3-Injection
- PCI DSS v3.2.1: PCI DSS (3.2.1) - 6.5.1 - Injection flaws - particularly SQL injection
- PCI DSS v4.0: PCI DSS (4.0) - 6.2.4 Vulnerabilities in software development
- SANS top 25: SANS top 25

## SQL\_Injection (Type)

Query Path: PHP/PHP\_Critical\_Risk/SQL\_Injection

CWE Id: 89

Total results: 4

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets user input from the @SourceElement element. This element's value then flows through the code without being properly sanitized or validated, and is eventually used in a database query in method @DestinationMethod at line @DestinationLine of @DestinationFile. This may enable an SQL Injection attack.

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002540 - CAT I The application must not be vulnerable to SQL Injection.
- CWE top 25: CWE top 25

## Reflected\_XSS (Type)

Query Path: PHP/PHP\_High\_Risk/Reflected\_XSS

CWE Id: 79

Total results: 93

Description: The method @DestinationMethod embeds untrusted data in generated output with @DestinationElement, at line @DestinationLine of @DestinationFile. This untrusted data is embedded into the output without proper sanitization or encoding, enabling an attacker to inject malicious code into the generated web-page. The attacker would be able to alter the returned web page by simply providing modified data in the user input @SourceElement, which is read by the @SourceMethod method at line @SourceLine of @SourceFile. This input then flows through the code straight to the output web page, without sanitization. This can enable a Reflected Cross-Site Scripting (XSS) attack.

Category:

- ASA Premium: [ASA Premium](#)
- ASD STIG 5.3: [APSC-DV-002490 - CAT I](#) The application must protect from Cross-Site Scripting (XSS) vulnerabilities.

## Client\_DOM\_Stored\_Code\_Injection (Type)

Query Path: JavaScript/JavaScript\_High\_Risk/Client\_DOM\_Stored\_Code\_Injection

CWE Id: 94

Total results: 1

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets user input for the @SourceElement element. The input flows to @DestinationMethod method, at line @DestinationLine of @DestinationFile without being properly filtered, encoded or sanitized. This could enable an attacker to inject and run arbitrary client code in the browser.

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002510 - CAT I The application must protect from command injection.
- CWE top 25: CWE top 25
- FISMA 2014: Configuration Management
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Verification and representation of input data
- NIST SP 800-53: SI-10 Information Input Validation (P1)

## Client\_DOM\_Stored\_XSS (Type)

Query Path: JavaScript/JavaScript\_High\_Risk/Client\_DOM\_Stored\_XSS

CWE Id: 79

Total results: 80

Description: The method @DestinationMethod embeds untrusted data in generated output with @DestinationElement, at line @DestinationLine of @DestinationFile. This untrusted data is embedded into the output without proper sanitization or encoding, enabling an attacker to inject malicious code into the generated web-page.

Category:

## Client\_DOM\_Code\_Injection (Type)

Query Path: JavaScript/JavaScript\_High\_Risk/Client\_DOM\_Code\_Injection

CWE Id: 94

Total results: 8

Description: The method @DestinationMethod embeds untrusted data in generated output with @DestinationElement, at line @DestinationLine of @DestinationFile. This untrusted data is embedded into the output without proper sanitization or encoding, enabling an attacker to inject malicious code into the generated web-page. The attacker can inject the malicious payload into the victim client, via external input @SourceElement. This is then processed by the client in the @SourceMethod method, at line @SourceLine of @SourceFile. The client evaluates the code and executes it.

## Absolute\_Path\_Traversal (Type)

Query Path: PHP/PHP\_High\_Risk/Absolute\_Path\_Traversal

CWE Id: 36

Total results: 10

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets dynamic data from the @SourceElement element. This element's value then flows through the code and is eventually used in a file path for local disk access in @DestinationMethod at line @DestinationLine of @DestinationFile. This may cause a Path Traversal vulnerability. Because of the way PHP wrappers work a specially crafted input from the @SourceElement element at line @SourceLine of @SourceFile can flow to @DestinationMethod at line @DestinationLine of @DestinationFile and cause an RCE, SSRF, filter bypass or another critical vulnerability.

Description: The application's @DestinationMethod method calls an OS (shell) command with @DestinationElement, at line @DestinationLine of @DestinationFile, using an untrusted string with the command to execute. This could allow an attacker to inject an arbitrary command, and enable a Command Injection attack. The attacker may be able to inject the executed command into the database, which is then retrieved by the application with @SourceElement, at line @SourceLine of @SourceFile, in the @SourceMethod method.

Category:

- ASA Premium: ASA Premium

## HttpOnly\_Cookie\_Flag\_Not\_Set (Type)

Query Path: PHP/PHP\_Medium\_Threat/HttpOnly\_Cookie\_Flag\_Not\_Set

CWE Id: 1004

Total results: 23

Description: The web application's @SourceMethod method creates a cookie @SourceElement, at line @SourceLine of @SourceFile, and returns it in the response. However, the application is not configured to automatically set the cookie with the "httpOnly" attribute, and the code does not explicitly add this to the cookie.

## Relative\_Path\_Traversal (Type)

Query Path: PHP/PHP\_Medium\_Threat/Relative\_Path\_Traversal

CWE Id: 23

Total results: 35

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets dynamic data from the @SourceElement element. This element's value then flows through the code and is eventually used in a file path for local disk access in @DestinationMethod at line @DestinationLine of @DestinationFile. This may cause a Path Traversal vulnerability.

Category:

- ASA Premium: ASA Premium
- CWE top 25: CWE top 25
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Verification and representation of input data

## Parameter\_Tampering (Type)

Query Path: PHP/PHP\_Medium\_Threat/Parameter\_Tampering

CWE Id: 472

Total results: 12

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets user input from element @SourceElement. This input is later concatenated by the application directly into a string variable containing SQL commands, without being validated. This string is then used in method @DestinationMethod to query the database @DestinationElement, at line @DestinationLine of @DestinationFile, without any additional filtering by the database. This could allow the user to tamper with the filter parameter.

Category:

## Client\_HTML5\_Insecure\_Storage (Type)

Query Path: JavaScript/JavaScript\_Medium\_Threat/Client\_HTML5\_Insecure\_Storage

CWE Id: 312

Total results: 1

Description: The application stores data @DestinationElement on the client, in an insecure manner, at line @DestinationLine of @DestinationFile.

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002340 - CAT II The application must implement approved cryptographic mechanisms to prevent unauthorized modification of organization-defined information at rest on organization-defined information system components.
- Base Preset: Base Preset
- FISMA 2014: Media Protection
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Security Functions
- NIST SP 800-53: SC-28 Protection of Information at Rest (P1)

## CSRF (Type)

Query Path: PHP/PHP\_Medium\_Threat/CSRF

CWE Id: 352

Total results: 10

Description: Method @SourceMethod at line @SourceLine of @SourceFile gets a parameter from a user request from @SourceElement. This parameter value flows through the code and is eventually used to access application state altering functionality. This may enable Cross-Site Request Forgery (CSRF).

Category:

- ASA Premium: ASA Premium
- ASD STIG 5.3: APSC-DV-002500 - CAT II The application must protect from Cross-Site Request Forgery (CSRF) vulnerabilities.
- CWE top 25: CWE top 25
- MOIS(KISA) Secure Coding 2021: MOIS(KISA) Verification and representation of input data
- NIST SP 800-53: SC-23 Session Authenticity (P1)
- OWASP ASVS: V13 API and Web Service
- OWASP Top 10 2013: A8-Cross-Site Request Forgery (CSRF)
- OWASP Top 10 2021: A1-Broken Access Control
- PCI DSS v3.2.1: PCI DSS (3.2.1) - 6.5.9 - Cross-site request forgery

CVE: [CVE-2016-10540](#)

Description: Minimatch is a minimal matching utility that works by converting glob expressions into JavaScript `RegExp` objects. The primary function, `minimatch(path, pattern)` in Minimatch 3.0.1 and earlier is vulnerable to ReDoS in the `pattern` parameter.

### Result 1 of 1 - Vulnerability

High • Recurrent • To Verify • Outdated: yes • Found First: 06 Sep, 2024 • Found Last: 06 Sep, 2024 • Result ID: IXTyJxa/KO/j3V/ZfxU4+c4vnvs= • First Scan ID: b94dfa0d-b075-4de0-a975-ef50cbd909fb

CVE: Cx89601373-08db

Description: NPM `debug` prior to 4.3.0 has a Memory Leak when creating `debug` instances inside a function which can have a significant impact in the Availability. This happens since the function `de bug` in the file `src/common.js` does not free up used memory.

## Npm-json5-0.5.1 (1 Result)

Package Name: [json5](#)

Version: 0.5.1

Total Results: 1

Category: [CWE-1321 ↗](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

High • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 •

Result ID: IS6pNLpQZFAfgNTJwRqh+VlnxCM= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [CVE-2022-46175](#)

Description: JSON5 is an extension to the popular JSON file format that aims to be easier to write and maintain by hand (e.g. for config files). The `parse` method of the JSON5 library version through 1.0.1 and 2.0.x through 2.2.1 does not restrict parsing of keys named `\_\_proto\_\_`, allowing specially crafted strings to pollute the prototype of the resulting object. This vulnerability pollutes the prototype of the object returned by `JSON5.parse` and not the global Object prototype, which is the commonly understood definition of Prototype Pollution. However, polluting the prototype of a single object can have a significant security impact for an application if the object is later used in trusted operations. This vulnerability could allow an attacker to set arbitrary and unexpected keys on the object returned from `JSON5.parse`. The actual impact will depend on how applications utilize the returned object and how they filter unwanted keys, but could include denial of service, cross-site scripting, the elevation of privilege, and in extreme cases, remote code execution. `JSON5.parse` should restrict parsing of `\_\_proto\_\_` keys when parsing JSON strings to objects. As a point of reference, the `JSON.parse` method included in JavaScript ignores `\_\_proto\_\_` keys. Simply changing `JSON5.parse` to `JSON.parse` in the examples above mitigates this vulnerability.

CVE: [CVE-2024-21910](#)

Description: A cross-site Scripting (XSS) vulnerability was discovered in the URL processing logic of the image and link plugins. The vulnerability allowed arbitrary JavaScript execution when updating an image or link using a specially crafted URL. This issue only impacted users while editing and the dangerous URLs were stripped in any content extracted from the editor. This impacts all users who are using TinyMCE versions through 5.9.2.

References: [Advisory](#) • [Issue](#) • [Commit](#) • [Release Note](#) • [Pull request](#) • [Commit](#)

## Result 2 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: 8dZf7K7uRbwqFO3FkrrYQvPh1DY= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [Cxdc71de4a-3a09](#)

Description: A cross-site scripting (XSS) vulnerability exists in TinyMCE in the URL sanitization logic of the core parser for form elements in versions prior to 5.7.1. The vulnerability allows arbitrary JavaScript execution when inserting a specially crafted piece of content into the editor using the clipboard or APIs, and then submitting the form. However, as TinyMCE does not allow forms to be submitted while editing, the vulnerability could only be triggered when the content was previewed or rendered outside of the editor.

References: [Advisory](#) • [Release Note](#) • [Pull request](#) • [Commit](#)

## Result 3 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: riQxYftU9N/sx8IC1RTsbpsiLXs= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [CVE-2024-21908](#)

Description: A cross-site scripting (XSS) vulnerability was discovered in the schema validation logic of the core parser. The vulnerability allowed arbitrary JavaScript execution when inserting a specially crafted piece of content into the editor using the clipboard or editor APIs. This malicious content could then end up in content published outside the editor, if no server-side sanitization was performed. This impacts all users who are using TinyMCE versions prior to 5.9.0.

#### Result 5 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: Qpc4kPrvvwG63+/7Y1v0jEWSsdU= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2024-29881

Description: TinyMCE is an open source rich text editor. A Cross-Site Scripting (XSS) vulnerability was discovered in TinyMCE's content loading and content inserting code. An SVG image could be loaded through an `object` or `embed` element and that image could potentially contain an XSS payload. This issue affects versions prior to 7.0.0. This vulnerability could be mitigated in versions 6.8.0 through 6.8.3 by changing the value for the `convert\_unsafe\_embeds` flag to `True`, instead of relying on its default `False` value. For 7.x versions, this flag is enabled by default for security reasons and does not require any additional changes.

#### Result 6 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: GlywXrDPZFW4qaHctukBVIT+D3M= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2024-38356

Description: TinyMCE is an open source rich text editor. A Cross-site Scripting (XSS) vulnerability was discovered in TinyMCE's content extraction code. When using the `noneditable\_regexp` option, specially crafted HTML attributes containing malicious code were able to be executed when content was extracted from the editor. This vulnerability has been patched in TinyMCE by ensuring that, when using the `noneditable\_regexp` option, any content within an attribute is properly verified to match the configured regular expression before being added. This vulnerability affects NPM-tinymce, PHP-tinymce/tinymce, and NuGet-TinyMCE versions through 5.10.9, 6.0.0 through 6.8.3, and 7.0.0 through 7.1.2.

References: [Advisory](#) • [Release Note](#) • [Commit](#) • [Commit](#)

#### Result 7 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: Sis/ZgcH5VdXVpkjv/cTi2WF924= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2024-38357

Description: TinyMCE is an open source rich text editor. A Cross-site Scripting (XSS) vulnerability was discovered in TinyMCE's content parsing code. This allowed specially crafted "noscript" elements containing malicious code to be executed when that content was loaded into the editor. This vulnerability has been patched in TinyMCE by ensuring that content within "noscript" elements is properly parsed. This vulnerability affects NPM-tinymce, PHP-tinymce/tinymce, and NuGet-TinyMCE versions through 5.10.9, 6.0.0 through 6.8.3, and 7.0.0 through 7.1.2.

References: [Advisory](#) • [Commit](#) • [Commit](#) • [Release Note](#)

## Result 8 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: Fd1/20TpZGNppQYscUJYuqf4ZeE= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2022-23494

Description: Tinymce is an open source rich text editor. A Cross-Site Scripting (XSS) vulnerability was discovered in versions prior to 5.10.7 and 6.0.x prior to 6.3.1 in the alert and confirm dialogs when the se dialogs were provided with malicious HTML content. This can occur in plugins that use the alert or confirm dialogs, such as in the `image` plugin, which presents these dialogs when certain errors occur. The vulnerability allowed arbitrary JavaScript execution when an alert presented in the TinyMCE UI for the current user. This vulnerability has been patched by ensuring HTML sanitization was still performed after unwrapping invalid elements. Users unable to upgrade may ensure the `images\_upload\_handler` returns a valid value as per the `images\_upload\_handler` documentation.

References: [Advisory](#) • [Commit](#) • [Release Note](#)

## Result 9 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: 9e2nz8xuVLuQyu1NIDEsGOX+2wo= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2023-45818

Description: TinyMCE is an open-source rich text editor. A mutation cross-site scripting (mXSS) vulnerability was discovered in TinyMCE's core undo and redo functionality. When a carefully-crafted HTML snippet passes the XSS sanitization layer, it is manipulated as a string by internal trimming functions before being stored in the undo stack. If the HTML snippet is restored from the undo stack, the combination of the string manipulation and reparative parsing by either the browser's native DOMParser API (TinyMCE 6) or the SaxParser API (TinyMCE 5) mutates the HTML maliciously, allowing an XSS payload to be executed. This vulnerability has been patched by ensuring HTML is trimmed using node-level manipulation instead of string manipulation. Users are advised to upgrade. There are no known workarounds for this vulnerability. This vulnerability affects NPM-tinymce, PHP-tinymce/tinymce, and NuGet-TinyMCE packages versions prior to 5.10.8, 6.0.x prior to 6.7.1.

References: [Advisory](#) • [Release Note](#) • [Commit](#) • [Pull request](#) • [Commit](#)

## Result 10 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: 1LYdjOxSz5VnJHYIBX5koociw78= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2023-45819

Description: TinyMCE is an open-source rich text editor. A cross-site scripting (XSS) vulnerability was discovered in TinyMCE's Notification Manager API. The vulnerability exploits TinyMCE's unfiltered notification system, which is used in error handling. The conditions for this exploit require carefully crafted malicious content to have been inserted into the editor and a notification to have been triggered. When a notification was opened, the HTML within the text argument was displayed unfiltered in the notification. The vulnerability allowed arbitrary JavaScript execution when a notification was presented in the TinyMCE UI for the current user. This issue could also be exploited by any integration that uses a TinyMCE notification to display unfiltered HTML content. This vulnerability affects TinyMCE versions through 5.10.7, and 6.0.0 through 6.7.0. This was fixed by ensuring that the HTML displayed in the notification is sanitized, preventing the exploit. Users are advised to upgrade. There are no known workarounds for this vulnerability.

## Result 11 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: E+YMHDapT2BHFHRuPWIDC7fgecE= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2024-29203

Description: TinyMCE is an open source rich text editor. A Cross-Site Scripting (XSS) vulnerability was discovered in TinyMCE's content insertion code. This allowed `iframe` elements containing malicious code to execute when inserted into the editor. These `iframe` elements are restricted in their permissions by same-origin browser protections, but could still trigger operations such as downloading of malicious assets. This issue affects versions through 6.7.3. This vulnerability is mitigated in versions 6.8.0 through 6.8.3 by changing the value of the `sandbox\_iframes` flag to `True`, instead of relying on its default `False` value. For 7.x versions, this flag is enabled by default and does not require any additional changes.

## Result 12 of 12 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: g6rj4mB/2wVhtuRHkKjk895Os= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: CVE-2023-48219

Description: TinyMCE is an open source rich text editor. A mutation cross-site scripting (mXSS) vulnerability was discovered in TinyMCE's core undo/redo functionality and other APIs and plugins. Text nodes within specific parents are not escaped upon serialization according to the HTML standard. If such text nodes contain a special character reserved as an internal marker, they can be combined with other HTML patterns to form malicious snippets. These snippets pass the initial sanitisation layer when the content is parsed into the editor body, but can trigger XSS when the special internal marker is removed from the content and re-parsed. This vulnerability affects NPM-tinymce, PHP-tinymce/tinymce, and NuGet-TinyMCE packages versions prior to 5.10.9, 6.0.x prior to 6.7.3.

CVE: CVE-2024-37890

Description: The ws is an open-source WebSocket client and server for Node.js. A request with a number of headers exceeding the "server.maxHeadersCount" threshold could be used to crash a ws server. In vulnerable versions of ws, the issue can be mitigated in the following ways: 1. Reduce the maximum allowed length of the request headers using the "--max-http-header-size=size" and/or the "maxHeaderSize" options so that no more headers than the "server.maxHeadersCount" limit can be sent. 2. Set "server.maxHeadersCount" to "0" so that no limit is applied. This issue affects the package ws versions 2.1.0 through 5.2.3, 6.0.0 through 6.2.2, 7.0.0 through 7.5.9, and 8.0.0 through 8.17.0.

## Npm-yauzl-2.10.0 (1 Result)

Package Name: [yauzl](#)

Version: 2.10.0

Total Results: 1

Category: [CWE-22](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

High • Recurrent • To Verify • Outdated: no • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 •  
Result ID: sFfExwam/3KPlbF32Kj+tJITY30= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [Cx6e7f2c1-dc59](#)

Description: The package `yauzl` is vulnerable to Arbitrary File Write implemented through improper validation of symlinks. The function `validateFileName` in the file `index.js` doesn't validate malicious symlink files when checking for path traversal attacks. It is possible to create a malicious archive containing symlinks which leads to the file decompression outside the original filesystem location. This can be abused to read/write files in an arbitrary location. This affects the three CIA impact metrics: Confidentiality, Integrity and Availability. All of the versions appear to be vulnerable, as the issue still has not been addressed and no fix is available.

References: [Issue](#)

## Npm-braces-2.3.2 (1 Result)

Package Name: [braces](#)

Version: 2.3.2

Total Results: 1

Category: [CWE-1050](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

High • Recurrent • To Verify • Outdated: yes • Found First: 10 Sep, 2024 • Found Last: 10 Sep, 2024 •  
Result ID: 1Hnm05SbMHa/L+hAmcyIg0/6blc= • First Scan ID: 3ca71214-4972-44a7-af1f-cb7b4759c621

CVE: [CVE-2024-4068](#)

Description: The NPM package "braces", versions prior to 3.0.3, fails to limit the number of characters it can handle, which could lead to Memory Exhaustion. In "lib/parse.js," if a malicious user sends "imbalanced braces" as input, the parsing will enter a loop, which will cause the program to start allocating heap memory without freeing it at any moment of the loop. Eventually, the JavaScript heap limit is reached, and the program will crash.

## Npm-micromatch-3.1.10 (1 Result)

Package Name: [micromatch](#)

Version: 3.1.10

Total Results: 1

Category: [CWE-1333](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 10 Sep, 2024 • Found Last: 10 Sep, 2024 • Result ID: cHG3+f3FyMbJpCrkkVajqWfOqLw= • First Scan ID: 3ca71214-4972-44a7-af1f-cb7b4759c621

CVE: [CVE-2024-4067](#)

Description: The NPM package "micromatch" prior to 4.0.8 is vulnerable to Regular Expression Denial of Service (ReDoS). The vulnerability occurs in "micromatch.braces()" in "index.js" because the pattern ":" will greedily match anything. By passing a malicious payload, the pattern matching will keep back tracking to the input while it doesn't find the closing bracket. As the input size increases, the consumption time will also increase until it causes the application to hang or slow down. There was a merged fix but further testing shows the issue still persists. This issue should be mitigated by using a safe pattern that won't start backtracking the regular expression due to its greedy matching.

### Result 1 of 1 - Vulnerability

Medium • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 • Result ID: atitO1BVnl8SEE5afvZvr8NShYs= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [CVE-2021-23566](#)

Description: The package nanoid before 3.1.31 are vulnerable to Information Exposure via the valueOf() function which allows to reproduce the last id generated.

## Npm-postcss-7.0.39 (1 Result)

Package Name: [postcss](#)

Version: [7.0.39](#)

Total Results: 1

Category: [CWE-74 ↗](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

[Medium](#) • Recurrent • To Verify • Outdated: yes • Found First: 10 Sep, 2024 • Found Last: 10 Sep, 2024 •

Result ID: RWHaGymTH13kjo4tFck38dID2Gs= • First Scan ID: 3ca71214-4972-44a7-af1f-cb7b4759c621

CVE: [CVE-2023-44270](#)

Description: An issue was discovered in postcss versions prior to 8.4.31. The vulnerability affects linters using PostCSS to parse external untrusted CSS. An attacker can prepare CSS in such a way that it will contain parts parsed by PostCSS as a CSS comment. After processing by PostCSS, it will be included in the PostCSS output in CSS nodes (rules, properties) despite being included in a comment.

## Npm-xml2js-0.4.17 (1 Result)

Package Name: [xml2js](#)

Version: [0.4.17](#)

Total Results: 1

Category: [CWE-1321 ↗](#)

Total Results: 1

### Result 1 of 1 - Vulnerability

[Medium](#) • Recurrent • To Verify • Outdated: yes • Found First: 17 Sep, 2024 • Found Last: 17 Sep, 2024 •

Result ID: mXPVsYcLUBa7SJbKXQMjss5Di7k= • First Scan ID: 52be79b0-2e03-44f2-949a-0bf75c33f124

CVE: [CVE-2023-0842](#)

Description: The xml2js in versions prior to 0.5.0 allows an external attacker to edit or add new properties to an object. This is possible because the application does not properly validate incoming JSON keys, thus allowing the "\_\_proto\_\_" property to be edited.

## Vulnerability Details

### Stored\_XSS (CWE 79)

#### What Is The Risk

A successful XSS exploit would allow an attacker to rewrite web pages and insert malicious scripts which would alter the intended output. This could include HTML fragments, CSS styling rules, arbitrary JavaScript, or references to third party code. An attacker could use this to steal users' passwords, collect personal data such as credit card details, provide false information, or run malware. From the victim's point of view, this is performed by the genuine website, and the victim would blame the site for incurred damage. An attacker could use legitimate access to the application to submit modified data to the application's data-store. This would then be used to construct the returned web page, triggering the attack.

#### What Can Cause It

The application creates web pages that include untrusted data, whether from user input, the application's database, or from other external sources. The untrusted data is embedded directly in the page's HTML, causing the browser to display it as part of the web page. If the input includes HTML fragments or JavaScript, these are displayed too, and the user cannot tell that this is not the intended page. The vulnerability is the result of directly embedding arbitrary data without first encoding it in a format that would prevent the browser from treating it like HTML or code instead of plain text. In order to exploit this vulnerability, an attacker would load the malicious payload into the data-store, typically via regular forms on other web pages. Afterwards, the application reads this data from the data-store, and embeds it within the web page as displayed for another user.

#### General Recommendations

- \* Fully encode all dynamic data, regardless of source, before embedding it in output.
  - \* Encoding should be context-sensitive. For example:
    - \* HTML encoding for HTML content
    - \* HTML Attribute encoding for data output to attribute values
    - \* JavaScript encoding for server-generated JavaScript
  - \* It is recommended to use the platform-provided encoding functionality, or known security libraries for encoding output.
  - \* Implement a Content Security Policy (CSP) with explicit whitelists for the application's resources only.
  - \* As an extra layer of protection, validate all untrusted data, regardless of source (note this is not a replacement for encoding).

Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:

- \* Data type
- \* Size
- \* Range
- \* Format
- \* Expected values
- \* In the 'Content-Type' HTTP response header, explicitly define character encoding (charset) for the entire page.
- \* Set the 'HTTPOnly' flag on the session cookie for "Defense in Depth", to prevent any successful XSS exploits from stealing the cookie.
  - \* Consider that many native PHP methods for sanitizing values, such as htmlspecialchars and htmlentities, do not inherently encode values for Javascript contexts and ignore certain enclosure characters such as apostrophe ('), quotes ("') and backticks (`'). Always consider the output context of inputs before choosing either of these functions as sanitizers.

### Second\_Order\_SQL\_Injection (CWE 89)

#### What Is The Risk

An attacker could directly access all of the system's data. The attacker would be able to steal any sensitive information stored by the system (such as personal user details or credit cards), and possibly change or erase existing data.

#### What Can Cause It

The application communicates with its database by sending a textual SQL query. The application creates the query by simply concatenating strings including data obtained from the database. Since that data may have been previously obtained from user input, and is neither checked for data type validity nor subsequently sanitized, the data could contain SQL commands that would be interpreted as such by the database.

## General Recommendations

1. Validate all data, regardless of source. Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values
3. Instead of concatenating strings:
  - \* Use secure database components such as stored procedures, parameterized queries, and object bindings (for commands and parameters).
  - \* An even better solution is to use an ORM library, such as EntityFramework, Hibernate, or iBatis.
4. Restrict access to database objects and functionality, according to the Principle of Least Privilege.

## SQL\_Injection (CWE 89)

### What Is The Risk

An attacker could directly access all of the system's data. Using simple tools and text editing, the attacker would be able to steal any sensitive information stored by the system (such as personal user details or credit cards), and possibly change or erase existing data.

### What Can Cause It

The application communicates with its database by sending a textual SQL query. The application creates the query by simply concatenating strings including the user's input. Since the user input is neither checked for data type validity nor subsequently sanitized, the input could contain SQL commands that would be interpreted as such by the database.

## General Recommendations

1. Validate all input, regardless of source. Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values.
3. Instead of concatenating strings:
  - \* Use secure database components such as stored procedures, parameterized queries, and object bindings (for commands and parameters).
  - \* An even better solution is to use an ORM library, such as EntityFramework, Hibernate, or iBatis.
4. Restrict access to database objects and functionality, according to the Principle of Least Privilege.

## Reflected\_XSS (CWE 79)

### What Is The Risk

A successful XSS exploit would allow an attacker to rewrite web pages and insert malicious scripts which would alter the intended output. This could include HTML fragments, CSS styling rules, arbitrary JavaScript, or references to third party code. An attacker could use this to steal users' passwords, collect personal data such as credit card details, provide false information, or run malware. From the victim's point of view, this is performed by the genuine website, and the victim would blame the site for incurred damage. The attacker could use social engineering to cause the user to send the website modified input, which will be returned in the requested web page.

### What Can Cause It

The application creates web pages that include untrusted data, whether from user input, the application's database, or from other external sources. The untrusted data is embedded directly in the page's HTML, causing the browser to display it as part of the web page. If the input includes HTML fragments or JavaScript, these are displayed too, and the user cannot tell that this is not the intended page. The vulnerability is the result of directly embedding arbitrary data without first encoding it in a format that would prevent the browser from treating it like HTML or code instead of plain text. Note that an attacker can exploit this vulnerability either by modifying the URL, or by submitting malicious data in the user input or other request fields.

## General Recommendations

- \* Fully encode all dynamic data, regardless of source, before embedding it in output.
  - \* Encoding should be context-sensitive. For example:
    - \* HTML encoding for HTML content
    - \* HTML Attribute encoding for data output to attribute values
    - \* JavaScript encoding for server-generated JavaScript
  - \* It is recommended to use the platform-provided encoding functionality, or known security libraries for encoding output.
  - \* Implement a Content Security Policy (CSP) with explicit whitelists for the application's resources only.
  - \* As an extra layer of protection, validate all untrusted data, regardless of source (note this is not a replacement for encoding).

Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:

- \* Data type
- \* Size
- \* Range
- \* Format
- \* Expected values
- \* In the `Content-Type` HTTP response header, explicitly define character encoding (charset) for the entire page.
- \* Set the `HTTPOnly` flag on the session cookie for "Defense in Depth", to prevent any successful XSS exploits from stealing the cookie.
- \* Consider that many native PHP methods for sanitizing values, such as `htmlspecialchars` and `htmlentities`, do not inherently encode values for Javascript contexts and ignore certain enclosure characters such as apostrophe ('), quotes ("') and backticks (`). Always consider the output context of inputs before choosing either of these functions as sanitizers.

## Unsafe\_Reflection (CWE 470)

### What Is The Risk

Reflections directly affected by user input may, at best, result in unexpected or unstable behavior. At worst, it may allow attackers to inject and execute malicious code, invoke unexpected methods or classes from within the code to bypass logic flow or manipulate data and more.

### What Can Cause It

Reflections are a method of coding wherein classes, methods or built-in functions are programmatically invoked by their name. If this name is dynamically determined from user inputs, then these inputs may change the flow of code, invoke unexpected or unintended code and, at times, allow injection of new, malicious code.

## General Recommendations

Avoid using any form of dynamic code evaluation, and specifically, avoid using reflections unless absolutely required.

- If dynamic evaluation is not required, use logic flow to determine which functions to run
- If dynamic evaluation is required, enforce a white-list of allowed code segments to ensure arbitrary code cannot be executed

## Prototype\_Pollution (CWE 1321)

### What Is The Risk

The risk varies as it highly depends on application's architecture. Allowing user inputs to overwrite internal language functionality will allow them to override and replace core code with malicious code, at some cases even execute it.

### What Can Cause It

JavaScript allows for new objects to copy the properties and methods from the prototype object. Modifying object's properties will affect other objects, both current running objects and post modification.

## General Recommendations

- Validate object properties prior assignment.
  - Prefer use of `Map` over `Object`.
  - Use of JSON schema validators are recommended.

## Deserialization\_of\_Untrusted\_Data (CWE 502)

## What Is The Risk

Deserialization of untrusted data may allow attackers to craft and provide a malicious object to the deserializing code. If a dangerous object is unsecurely serialized, it may result in execution of code or operating system commands, by invoking classes or methods potentially available to the object during the deserialization process. Additionally, deserialization may bypass logical object validation. Since deserialization often uses its own means of constructing a new object from the serialized data, it may bypass checks enforced in constructors or setters, which would allow attackers to deserialize an object whose properties are not validated, incorrect or outright malicious. This may lead to unexpected behavior, affecting logic in ways that are entirely dependent on implementation. In PHP, deserialization will only affect objects in scope, and is only guaranteed to trigger the `\_\_wakeup()` method when an object is serialized, and `\_\_destruct()` after it completes its lifecycle; this is because many "dangerous" methods in PHP are actually language constructs, and may not be invoked via serialization. However - other magic methods, that are not triggered in the moment deserialization occurs, can be used in exploitation when the object is used or destroyed, such as `\_\_toString()`, `\_\_call()`, and others. This means that deserialization may still enable logic bypasses or exploitation of existing objects, but only if they employ magic methods whose implementation would pose a threat to the application. For example - a destructor that creates a file based on instance variables, which can be manipulated via deserialization, could allow attackers to use this class destructor to write a file with malicious code.

## What Can Cause It

Object serialization and deserialization is integral to the process of remoting, wherein objects are passed between code instances over an intermediary medium, such as over a network. During deserialization, a new object is constructed from a serialized object provided over the medium; however, if the object being serialized is untrusted, an unexpected and potentially dangerous object can be provided.

## General Recommendations

- \* Where possible, do not pass serialized object between remote instances. Instead, consider passing value primitives between instances and use these values to populate a newly constructed object.
  - \* If required, use a whitelist approach to passed objects. Always ensure the passed object is known, trusted and expected. Do not dynamically construct an object from any source unless the object has been verified and is of a trusted, known type, and may not contain untrusted objects within it.
  - \* When choosing a serializer - always consult vendor documentation, best practices and even known exploitation techniques to ensure that the serializer chosen and deployed is defensible, securely configured, and does not allow any potentially dangerous objects.

## Dangerous\_File\_Inclusion (CWE 829)

## What Is The Risk

If an attacker can select the name of the library, or the location of the code file that is loaded by the application, they would be able to cause the application to execute arbitrary code. This effectively allows the attacker to control the code run by the application.

## What Can Cause It

The application uses untrusted data to specify the library or code file, without proper sanitization. This causes the application to load any arbitrary code, as specified. The loaded code will then be executed.

## General Recommendations

- \* Do not dynamically load code libraries, especially not based on user input.
  - \* If it is necessary to use untrusted data to select the library to be loaded, verify the selected library name matches a predefined set of whitelisted library names. Alternatively, use the value as an identifier to select from the whitelisted libraries.
  - \* Validate any untrusted data used to load or process libraries or code files by performing an integrity check on the requested resource.
    - In older PHP versions, make sure `allow_url_fopen` is disabled in `php.ini`

## Client\_DOM\_XSS (CWE 79)

## What Is The Risk

A successful XSS exploit would allow an attacker to rewrite web pages and insert malicious scripts which would alter the intended output. This could include HTML fragments, CSS styling rules, arbitrary JavaScript, or references to third party code. An attacker could use this to steal users' passwords, collect personal data such as credit card details, provide false information, or run malware. From the victim's point of view, this is performed by the genuine website, and the victim would blame the site for incurred damage. An additional risk with DOM XSS is that, unlike reflected or stored XSS, tainted values do not have to go through the server. Since the server is not involved in sanitization of these inputs, server-side validation is not likely to be aware XSS attacks have been occurring, and any server-side security solutions, such as a WAF, are likely to be ineffective in DOM XSS mitigation.

## What Can Cause It

The application creates web pages that include untrusted data, whether from user input, the application's database, or from other external sources. The untrusted data is embedded directly in the page's HTML, causing the browser to display it as part of the web page. If the input includes HTML fragments or JavaScript, these are displayed too, and the user cannot tell that this is not the intended page. The vulnerability is the result of directly embedding arbitrary data without first encoding it in a format that would prevent the browser from treating it like HTML or code instead of plain text. When a DOM XSS occurs, it is the client-side code itself that manipulates the local web-page's DOM, and introduces malicious content.

## General Recommendations

- \* Fully encode all dynamic data, regardless of source, before embedding it in output.
  - \* Encoding should be context-sensitive. For example:
    - \* HTML encoding for HTML content
    - \* HTML Attribute encoding for data output to attribute values
    - \* JavaScript encoding for server-generated JavaScript
  - \* It is recommended to use the platform-provided encoding functionality, or known security libraries for encoding output.
  - \* Implement a Content Security Policy (CSP) with explicit whitelists for the application's resources only.
  - \* As an extra layer of protection, validate all untrusted data, regardless of source (note this is not a replacement for encoding).
- Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values
  - \* In the `Content-Type` HTTP response header, explicitly define character encoding (charset) for the entire page.
  - \* Set the `HTTPOnly` flag on the session cookie for "Defense in Depth", to prevent any successful XSS exploits from stealing the cookie.

## Client\_DOM\_Stored\_Code\_Injection (CWE 94)

### What Is The Risk

An attacker could potentially rewriting web pages and inserting malicious scripts. The attacker can then pretend to be the original website, which would enable the attacker to steal the user's password, request the user's credit card information, provide false information, or run malware. From the victim's point of view, this is the original website, and the victim would blame the site for incurred damage. The attacker may be able to inject his malicious payload into the victim client's storage, such as cookies, local storage, or other client-side storage functionality. This would enable the attacker to gain control of the user's experience with the client application, hijacking the client to alter the displayed web pages, mount phishing attacks, and execute arbitrary scripts.

## What Can Cause It

The application web page performs some action by creating and running client-side code that includes concatenated user input. If the user input contains malicious code, the executed code could contain activities engineered by an attacker.

## General Recommendations

- Avoid any dynamic execution, or evaluation of code (such as `eval`, `setTimeout`, `setInterval` with user input).
  - If dynamic execution is necessary, instead of using user data (including any client-side variable data such as the URL), use only hard-coded data or trusted data from the server.

## Client\_DOM\_Stored\_XSS (CWE 79)

### What Is The Risk

A successful XSS exploit would allow an attacker to rewrite web pages and insert malicious scripts which would alter the intended output. This could include HTML fragments, CSS styling rules, arbitrary JavaScript, or references to third party code. An attacker could use this to steal users' passwords, collect personal data such as credit card details, provide false information, or run malware. From the victim's point of view, this is performed by the genuine website, and the victim would blame the site for incurred damage. An additional risk with DOM XSS is that, unlike reflected or stored XSS, tainted values do not have to go through the server. Since the server is not involved in sanitization of these inputs, server-side validation is not likely to not be aware XSS attacks have been occurring, and any server-side security solutions, such as a WAF, are likely to be ineffective in DOM XSS mitigation.

## What Can Cause It

The application creates web pages that include untrusted data, whether from user input, the application's database, or from other external sources. The untrusted data is embedded directly in the page's HTML, causing the browser to display it as part of the web page. If the input includes HTML fragments or JavaScript, these are displayed too, and the user cannot tell that this is not the intended page. The vulnerability is the result of directly embedding arbitrary data without first encoding it in a format that would prevent the browser from treating it like HTML or code instead of plain text. When a DOM XSS occurs, it is the client-side code itself that manipulates the local web-page's DOM, extracting data from some client-based storage, introducing potentially malicious content.

## General Recommendations

- \* Fully encode all dynamic data, regardless of source, before embedding it in output.
  - \* Encoding should be context-sensitive. For example:
    - \* HTML encoding for HTML content
    - \* HTML Attribute encoding for data output to attribute values
    - \* JavaScript encoding for server-generated JavaScript
  - \* It is recommended to use the platform-provided encoding functionality, or known security libraries for encoding output.
  - \* Implement a Content Security Policy (CSP) with explicit whitelists for the application's resources only.
  - \* As an extra layer of protection, validate all untrusted data, regardless of source (note this is not a replacement for encoding).
- Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values
  - \* In the `Content-Type` HTTP response header, explicitly define character encoding (charset) for the entire page.
  - \* Set the `HTTPOnly` flag on the session cookie for "Defense in Depth", to prevent any successful XSS exploits from stealing the cookie.

## Client\_DOM\_Code\_Injection (CWE 94)

### What Is The Risk

A successful XSS exploit would allow an attacker to rewrite web pages and insert malicious scripts which would alter the intended output. This could include HTML fragments, CSS styling rules, arbitrary JavaScript, or references to third party code. An attacker could use this to steal users' passwords, collect personal data such as credit card details, provide false information, or run malware. From the victim's point of view, this is performed by the genuine website, and the victim would blame the site for incurred damage. An additional risk with DOM XSS is that, unlike reflected or stored XSS, tainted values do not have to go through the server. Since the server is not involved in sanitization of these inputs, server-side validation is not likely to be aware XSS attacks have been occurring, and any server-side security solutions, such as a WAF, are likely to be ineffective in DOM XSS mitigation. The attacker would use social engineering techniques to convince the victim to use the attacker's code, either via a malformed link or otherwise. This will enable the attacker to gain control of the user's experience with the web application, hijacking the client to alter the displayed web pages, mount phishing attacks, and execute arbitrary scripts.

### What Can Cause It

The application creates web pages that include untrusted data, whether from user input, the application's database, or from other external sources. The untrusted data is embedded directly in the page's HTML, causing the browser to display it as part of the web page. If the input includes HTML fragments or JavaScript, these are displayed too, and the user cannot tell that this is not the intended page. The vulnerability is the result of directly embedding arbitrary data without first encoding it in a format that would prevent the browser from treating it like HTML or code instead of plain text. When a DOM XSS occurs, it is the client-side code itself that manipulates the local web-page's DOM, and introduces malicious content. In this case, the untrusted input is read by the client, and evaluated as client-side code.

## General Recommendations

- \* Fully encode all dynamic data, regardless of source, before embedding it in output.
  - \* Encoding should be context-sensitive. For example:
    - \* HTML encoding for HTML content
    - \* HTML Attribute encoding for data output to attribute values
    - \* JavaScript encoding for server-generated JavaScript
  - \* It is recommended to use the platform-provided encoding functionality, or known security libraries for encoding output.
  - \* Implement a Content Security Policy (CSP) with explicit whitelists for the application's resources only.
  - \* As an extra layer of protection, validate all untrusted data, regardless of source (note this is not a replacement for encoding).

Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:

- \* Data type
- \* Size
- \* Range
- \* Format
- \* Expected values
- \* In the `Content-Type` HTTP response header, explicitly define character encoding (charset) for the entire page.
- \* Set the 'HTTPOnly' flag on the session cookie for "Defense in Depth", to prevent any successful XSS exploits from stealing the cookie.
- \* On the client-side, do not use any form of dynamic code evaluation with any untrusted data. Dynamic evaluation is only allowed with hard-coded commands.

## Absolute\_Path\_Traversal (CWE 36)

### What Is The Risk

An attacker could define arbitrary file path for the application to use, potentially leading to:

- \* Stealing sensitive files, such as configuration or system files
- \* Overwriting files such as program binaries, configuration files, or system files
- \* Deleting critical files, causing denial of service (DoS). In addition to common path traversal issues - allowing attackers to provide absolute paths in PHP is often more severe, due to PHP protocol wrappers and how they work. Protocol wrappers allow various protocols to be acted on using the same functions (e.g. `file_get_contents`, `file_exists`) using various schemes (e.g. `'file://'`, `'phar://'`, `'http://'`). This will often lead to unexpected behavior, depending on implementation and PHP configuration. For example, if an attacker can control a value passed to a file path call they may be able to:
  - Perform remote code execution (RCE) with `'phar://'` deserialization attacks
  - Perform server-side request forgery (SSRF) with `'http://'`
  - Filter bypass with `'php://filter'` and `'data://'`

### What Can Cause It

The application uses user input in the file path for accessing files on the application server's local disk.

## General Recommendations

1. Ideally, avoid depending on dynamic data for file selection.
2. Validate all input, regardless of source. Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values
3. Accept dynamic data only for the filename, not for the path and folders.
4. Ensure that file path is fully canonicalized.
5. Explicitly limit the application to use a designated folder that is separate from the application's binary folder.
6. Restrict the privileges of the application's OS user to necessary files and folders. The application should not be able to write to the application's binary folder, and should not read anything outside of the application folder and data folder.

## Use\_of\_Cryptographically\_Weak\_PRNG (CWE 338)

### What Is The Risk

Depending on what this random value is used for, an attacker with knowledge of the PRNG used would be able to predict the next values generated, or previously generated values, based on sources often used to derive certain randomness; however, while they may seem random, large statistical samples would demonstrate that they are insufficiently random, producing a much smaller space of possible "random" values than a truly random sample would. In the context of cryptography, this could enable an attacker to derive or guess the value, and thus crack the cryptographic mechanism or its outputs.

## What Can Cause It

The application uses a weak method of generating pseudo-random values, such that other numbers could be determined from a relatively small sample size. Since the pseudo-random number generator used is designed for statistically uniform distribution of values, it is approximately deterministic. Thus, after collecting a few generated values, it would be possible for an attacker to calculate past or future values. These values are then used as parameters in a cryptographic function. If an attacker were to obtain the original value from the weak PRNG, they may be able to predict or crack values produced by the cryptographic function.

## General Recommendations

- Always use a cryptographically secure pseudo-random number generator, instead of basic random methods, particularly when dealing with a security context such as cryptographic functions
  - Use the cryptorandom generator that is built-in to your language or platform, and ensure it is securely seeded. Do not seed the generator with a weak, non-random seed. (In most cases, the default is securely random).
  - Ensure you use a long enough random value, thus making brute-force attacks unfeasible.

## Plaintext\_Storage\_of\_a\_Password (CWE 256)

### What Is The Risk

Passwords that are stored in plaintext outside of a secure container would be trivial to read, if retrieved by an attacker. Leaked passwords could then be used to authenticate to other sensitive resources, to perform actions and retrieve additional information.

## What Can Cause It

A password was stored in plaintext, outside of a secure container such as a password hashing algorithm or data encryption.

## General Recommendations

### Generic Guidance:

- Always use strong, modern algorithms for encryption, hashing, and so on.
- Do not use weak, outdated, or obsolete algorithms.
- Ensure you select the correct cryptographic mechanism according to the specific requirements.
- Passwords should be protected with a dedicated password protection scheme, such as bcrypt, scrypt, PBKDF2, or Argon2.

### Specific Recommendations:

- Do not use SHA-1, MD5, or any other weak hash algorithm to protect passwords or personal data. Instead, use a stronger hash such as SHA-256 when a secure hash is required.
- Do not use DES, 3DES, RC2, or any other weak encryption algorithm to protect passwords or personal data. Instead, use a stronger encryption algorithm such as AES to protect personal data.
- Do not use weak encryption modes such as ECB, or rely on insecure defaults. Explicitly specify a stronger encryption mode, such as GCM.
- For symmetric encryption, use a key length of at least 256 bits.

## Stored\_Unsafe\_Reflection (CWE 470)

### What Is The Risk

Reflections directly affected by user input may, at best, result in unexpected or unstable behavior. At worst, it may allow attackers to inject and execute malicious code, invoke unexpected methods or classes from within the code to bypass logic flow or manipulate data and more.

## What Can Cause It

Reflections are a method of coding wherein classes, methods or built-in functions are programmatically invoked by their name. If this name is dynamically determined from user inputs, then these inputs may change the flow of code, invoke unexpected or unintended code and, at times, allow injection of new, malicious code.

## General Recommendations

Avoid using any form of dynamic code evaluation, and specifically, avoid using reflections unless absolutely required.

- If dynamic evaluation is not required, use logic flow to determine which functions to run
- If dynamic evaluation is required, enforce a white-list of allowed code segments to ensure arbitrary code cannot be executed

## Missing\_HSTS\_Header (CWE 346)

## What Is The Risk

Failure to set an HSTS header and provide it with a reasonable "max-age" value of at least one year may leave users vulnerable to Man-in-the-Middle attacks.

## What Can Cause It

Many users browse to websites by simply typing the domain name into the address bar, without the protocol prefix. The browser will automatically assume that the user's intended protocol is HTTP, instead of the encrypted HTTPS protocol. When this initial request is made, an attacker can perform a Man-in-the-Middle attack and manipulate it to redirect users to a malicious web-site of the attacker's choosing. To protect the user from such an occurrence, the HTTP Strict Transport Security (HSTS) header instructs the user's browser to disallow use of an unsecure HTTP connection to the the domain associated with the HSTS header. Once a browser that supports the HSTS feature has visited a web-site and the header was set, it will no longer allow communicating with the domain over an HTTP connection. Once an HSTS header was issued for a specific website, the browser is also instructed to prevent users from manually overriding and accepting an untrusted SSL certificate for as long as the "max-age" value still applies. The recommended "max-age" value is for at least one year in seconds, or 31536000.

## General Recommendations

- \* Before setting the HSTS header - consider the implications it may have:
  - \* Forcing HTTPS will prevent any future use of HTTP, which could hinder some testing
  - \* Disabling HSTS is not trivial, as once it is disabled on the site, it must also be disabled on the browser
  - \* Set the HSTS header either explicitly within application code, or using web-server configurations.
  - \* Ensure the "max-age" value for HSTS headers is set to 31536000 to ensure HSTS is strictly enforced for at least one year.
  - \* Include the "includeSubDomains" to maximize HSTS coverage, and ensure HSTS is enforced on all sub-domains under the current domain
    - \* Note that this may prevent secure browser access to any sub-domains that utilize HTTP; however, use of HTTP is very severe and highly discouraged, even for websites that do not contain any sensitive information, as their contents can still be tampered via Man-in-the-Middle attacks to phish users under the HTTP domain.
  - \* Once HSTS has been enforced, submit the web-application's address to an HSTS preload list - this will ensure that, even if a client is accessing the web-application for the first time (implying HSTS has not yet been set by the web-application), a browser that respects the HSTS preload list would still treat the web-application as if it had already issued an HSTS header. Note that this requires the server to have a trusted SSL certificate, and issue an HSTS header with a maxAge of 1 year (31536000)
  - \* Note that this query is designed to return one result per application. This means that if more than one vulnerable response without an HSTS header is identified, only the first identified instance of this issue will be highlighted as a result. If a misconfigured instance of HSTS is identified (has a short lifespan, or is missing the "includeSubDomains" flag), that result will be flagged. Since HSTS is required to be enforced across the entire application to be considered a secure deployment of HSTS functionality, fixing this issue only where the query highlights this result is likely to produce subsequent results in other sections of the application; therefore, when adding this header via code, ensure it is uniformly deployed across the entire application. If this header is added via configuration, ensure that this configuration applies to the entire application.
  - \* Note that misconfigured HSTS headers that do not contain the recommended max-age value of at least one year or the "includeSubDomains" flag will still return a result for a missing HSTS header.

## Stored\_Command\_Injection (CWE 77)

## What Is The Risk

An attacker could run arbitrary system-level OS commands on the application server host. Depending on the application's OS permissions, these could include:

- \* File actions (read / create / modify / delete)
- \* Open a network connection to the attacker's server
- \* Start and stop system services
- \* Modify the running application
- \* Complete server takeover

## What Can Cause It

The application runs an OS system-level command to complete it's task, rather than via the application code. The command includes untrusted data, that may be controllable by an attacker. This untrusted string may contain malicious system-level commands engineered by an attacker, which could be executed as though the attacker were running commands directly on the application server. In this case, the application reads the command from the database, and passes it as a string to the Operating System. The attacker may be able to load the malicious payload into the database fields beforehand, causing the application to load that command. This unvalidated data is then executed by the OS as a system command, running with the same system privileges as the application.

## General Recommendations

- \* Refactor the code to avoid any direct shell command execution. Instead, use platform provided APIs or library calls.
  - \* If it is impossible to remove the command execution, execute only static commands that do not include dynamic, user-controlled data.
    - \* Validate all input, regardless of source. Validation should be based on a whitelist: accept only data fitting a specified format, rather than rejecting bad patterns (blacklist). Parameters should be limited to an allowed character set, and non-validated input should be dropped. In addition to characters, check for:
      - \* Data type
      - \* Size
      - \* Range
      - \* Format
      - \* Expected values
    - \* In order to minimize damage as a measure of defense in depth, configure the application to run using a restricted user account that has no unnecessary OS privileges.
      - \* If possible, isolate all OS commands to use a separate dedicated user account that has minimal privileges only for the specific commands and files used by the application, according to the Principle of Least Privilege.
      - \* If absolutely necessary to call a system command or execute external program with user input, do not concatenate the user input with the command without sanitization. Use methods designed for this purpose, such as `escapeshellarg` and `escapeshellcmd`, where appropriate.

## HttpOnly\_Cookie\_Flag\_Not\_Set (CWE 1004)

### What Is The Risk

Cookies that contain the user's session identifier, and other sensitive application cookies, are typically accessible by client-side scripts, such as JavaScript. Unless the web application explicitly prevents this using the "httpOnly" cookie flag, these cookies could be read and accessed by malicious client scripts, such as Cross-Site Scripting (XSS). This flag would mitigate the damage done in case XSS vulnerabilities are discovered, according to Defense in Depth.

### What Can Cause It

The web application framework, by default, does not set the "httpOnly" flag for the application's sessionid cookie and other sensitive application cookies. Likewise, the application does not explicitly use the "httpOnly" cookie flag, thus allowing client scripts to access the cookies by default.

## General Recommendations

- Always set the "httpOnly" flag for any sensitive server-side cookie.
  - It is highly recommended to implement HTTP Strict Transport Security (HSTS) in order to ensure that the cookie will be sent over a secured channel.
    - Explicitly set the "httpOnly" flag for each cookie set by the application.
    - In particular, explicitly set the `\$httponly` parameter to true, any time a cookie is added to the response with `setcookie()` or `setrawcookie()`.
      - Preferably, configure PHP to automatically set httpOnly on all cookies by adding `session.cookie\_httponly = true` to `php.ini`, or by calling `ini\_set('session.cookie\_httponly', true);`
      - Alternatively, enforce strong defaults by setting the session parameters for each session, using `session\_set\_cookie\_params()` with `\$httpOnly` set to `true`.
        - If the cookie is being written directly to the response headers, e.g. via the `header()` method with the ``Set-Cookie:`` header name, append `";httpOnly;"` to the end of the cookie value.

## SSRF (CWE 918)

### What Is The Risk

An attacker can abuse this flaw to make arbitrary requests, originating from the application server. This can be exploited to scan internal services; proxy attacks into a protected network; bypass network controls; download unauthorized files; access internal services and management interfaces; and possibly control the contents of requests and even steal server credentials.

### What Can Cause It

The application accepts a URL (or other data) from the user, and uses this to make a request to another remote server. However, the attacker can inject an arbitrary URL into the request, causing the application to connect to any server the attacker wants. Thus, the attacker can abuse the application to gain access to services that would not otherwise be accessible, and cause the request to ostensibly originate from the application server.

## General Recommendations

- \* Do not connect to arbitrary services based on user input.
  - \* If possible, the application should have the user's browser retrieve the desired information directly.
  - \* If it is necessary for the application to proxy the request on the server, explicitly whitelist the allowed target URLs, and do not include any sensitive server information.

## SSL\_Verification\_Bypass (CWE 599)

### What Is The Risk

If the SSL/TLS library is configured to disable verification of the certificate's properties, such as trust chain, hostname, expiry and more - it is possible to cause the application to utilize an unvalidated certificate. This may allow an attacker to intercept the client requests, provide their own forged server certificate, and perform an active Man-in-the-Middle attacks - even over HTTPS. Thus an attacker would have complete access to the content of requests and responses, reading any secret information and tampering any sensitive data, including user credentials.

### What Can Cause It

The application utilizes HTTPS, but is explicitly configured to disable verification of certificate authenticity. If the certificate signer is not verified all the way up to a trusted certificate authority, it is possible to issue a bogus certificate, and have it be accepted by the application. Since the application does not enforce the signing certificate is already configured in the system's trusted root certificate store, it is possible to simply use a self-signed certificate, with any user- or server-name, and the application will trust it.

### General Recommendations

#### Generic Guidance:

- \* Properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.
- \* Properly configure all parameters of HTTPS.
- \* Never disable certificate verification.

## Relative\_Path\_Traversal (CWE 23)

### What Is The Risk

An attacker could define arbitrary file path for the application to use, potentially leading to:  
\* Stealing sensitive files, such as configuration or system files  
\* Overwriting files such as program binaries, configuration files, or system files  
\* Deleting critical files, causing denial of service (DoS).

### What Can Cause It

The application uses user input in the file path for accessing files on the application server's local disk.

### General Recommendations

1. Ideally, avoid depending on dynamic data for file selection.
2. Validate all input, regardless of source. Validation should be based on a whitelist: accept only data fitting a specified structure, rather than reject bad patterns. Check for:
  - \* Data type
  - \* Size
  - \* Range
  - \* Format
  - \* Expected values
4. Accept dynamic data only for the filename, not for the path and folders.
5. Ensure that file path is fully canonicalized.
6. Explicitly limit the application to use a designated folder that is separate from the applications binary folder.
7. Restrict the privileges of the application's OS user to necessary files and folders. The application should not be able to write to the application binary folder, and should not read anything outside of the application folder and data folder.

## Privacy\_Violation (CWE 359)

### What Is The Risk

A user's personal information could be stolen by a malicious programmer, or an attacker that intercepts the data.

### What Can Cause It

The application sends user information, such as passwords, account information, or credit card numbers, outside the application, such as writing it to a local text or log file or sending it to an external web service.

## General Recommendations

1. Personal data should be removed before writing to logs or other files.
2. Review the need and justification of sending personal data to remote web services.

## Parameter\_Tampering (CWE 472)

### What Is The Risk

A malicious user could access other users' information. By requesting information directly, such as by an account number, authorization may be bypassed and the attacker could steal confidential or restricted information (for example, a bank account balance), using a direct object reference.

### What Can Cause It

The application provides user information without filtering by user ID. For example, it may provide information solely by a submitted account ID. The application concatenates the user input directly into the SQL query string, without any additional filtering. The application also does not perform any validation on the input, nor constrain it to a pre-computed list of acceptable values.

## General Recommendations

### Generic Guidance:

- \* Enforce authorization checks before providing any access to sensitive data, including the specific object reference.
- \* Explicitly block access to any unauthorized data, especially to other users' data.
- \* If possible, avoid allowing the user to request arbitrary data by simply sending a record ID. For example, instead of having the user send an account ID, the application should look up the account ID for the current authenticated user session.

### Specific Mitigation:

- \* Do not concatenate user input directly into SQL queries.
- \* Include a user-specific identifier as a filter in the WHERE clause of the SQL query.
- \* Map the user input to an indirect reference, e.g. via a prepared list of allowable values.

## Missing\_HSTS\_Header (CWE 346)

### What Is The Risk

Failure to set an HSTS header and provide it with a reasonable "max-age" value of at least one year may leave users vulnerable to Man-in-the-Middle attacks.

### What Can Cause It

Many users browse to websites by simply typing the domain name into the address bar, without the protocol prefix. The browser will automatically assume that the user's intended protocol is HTTP, instead of the encrypted HTTPS protocol. When this initial request is made, an attacker can perform a Man-in-the-Middle attack and manipulate it to redirect users to a malicious web-site of the attacker's choosing. To protect the user from such an occurrence, the HTTP Strict Transport Security (HSTS) header instructs the user's browser to disallow use of an unsecure HTTP connection to the the domain associated with the HSTS header. Once a browser that supports the HSTS feature has visited a web-site and the header was set, it will no longer allow communicating with the domain over an HTTP connection. Once an HSTS header was issued for a specific website, the browser is also instructed to prevent users from manually overriding and accepting an untrusted SSL certificate for as long as the "max-age" value still applies. The recommended "max-age" value is for at least one year in seconds, or 31536000.

## General Recommendations

- \* Before setting the HSTS header - consider the implications it may have:
  - \* Forcing HTTPS will prevent any future use of HTTP, which could hinder some testing
  - \* Disabling HSTS is not trivial, as once it is disabled on the site, it must also be disabled on the browser
  - \* Set the HSTS header either explicitly within application code, or using web-server configurations.
  - \* Ensure the "max-age" value for HSTS headers is set to 31536000 to ensure HSTS is strictly enforced for at least one year.
  - \* Include the "includeSubDomains" to maximize HSTS coverage, and ensure HSTS is enforced on all sub-domains under the current domain
    - \* Note that this may prevent secure browser access to any sub-domains that utilize HTTP; however, use of HTTP is very severe and highly discouraged, even for websites that do not contain any sensitive information, as their contents can still be tampered via Man-in-the-Middle attacks to phish users under the HTTP domain.
- \* Once HSTS has been enforced, submit the web-application's address to an HSTS preload list - this will ensure that, even if a client is accessing the web-application for the first time (implying HSTS has not yet been set by the web-application), a browser that respects the HSTS preload list would still treat the web-application as if it had already issued an HSTS header. Note that this requires the server to have a trusted SSL certificate, and issue an HSTS header with a maxAge of 1 year (31536000)
  - \* Note that this query is designed to return one result per application. This means that if more than one vulnerable response without an HSTS header is identified, only the first identified instance of this issue will be highlighted as a result. If a misconfigured instance of HSTS is identified (has a short lifespan, or is missing the "includeSubDomains" flag), that result will be flagged. Since HSTS is required to be enforced across the entire application to be considered a secure deployment of HSTS functionality, fixing this issue only where the query highlights this result is likely to produce subsequent results in other sections of the application; therefore, when adding this header via code, ensure it is uniformly deployed across the entire application. If this header is added via configuration, ensure that this configuration applies to the entire application.
  - \* Note that misconfigured HSTS headers that do not contain the recommended max-age value of at least one year or the "includeSubDomains" flag will still return a result for a missing HSTS header.

## Client\_Privacy\_Violation (CWE 359)

### What Is The Risk

A user's personal information could be stolen by a malicious programmer, or an attacker that intercepts the data.

### What Can Cause It

The application sends user information, such as passwords, account information, or credit card numbers, outside the application, such as writing it to a local text or log file or sending it to an external web service.

## General Recommendations

1. Personal data should be removed before writing to logs or other files.
2. Review the need and justification of sending personal data to remote web services.

## Client\_HTML5\_Insecure\_Storage (CWE 312)

### What Is The Risk

An attacker that has access to a user's client device, will be able to retrieve stored information, such as user's sensitive personal data (PII) from the client storage. Use of this storage will also increase exposure of its content to theft via other means, such as cross-site scripting (XSS). This would be detrimental to the user and harm their privacy, and could cause damage to reputation, financial loss, and even lead to identity theft.

### What Can Cause It

The application stores data, which may contain PII (Personally Identifiable Information), on the client browser or device. The application uses insecure forms of storage, which do not inherently provide any protection from unauthorized access. This data is not encrypted or sanitized before being stored, thus a malicious entity with access to the device or browser could easily retrieve the user's data.

## General Recommendations

- \* Avoid storing sensitive data, such as PII, on unprotected clients.
  - \* If PII or other sensitive data must be stored on the client, ensure it is encrypted or otherwise protected.

## CSRF (CWE 352)

## What Is The Risk

An attacker could cause the victim to perform any action for which the victim is authorized, such as transferring funds from the victim's account to the attacker's. The action will be logged as being performed by the victim, in the context of their account, and potentially without their knowledge that this action has occurred.

## What Can Cause It

The application performs some action that modifies database contents, based purely on HTTP request content, and does not require per-request renewed authentication (such as transaction authentication or a synchronizer token), instead relying solely on session authentication. This means that an attacker could use social engineering to cause a victim to browse to a link which contains a transaction request to the vulnerable application, submitting that request from the user's browser. Once the application receives the request, it would trust the victim's session, and would perform the action. This type of attack is known as Cross-Site Request Forgery (CSRF). A Cross-Site Request Forgery attack relies on the trust between a server and an authenticated client. By only validating the session, the server ensures that a request has emerged from a client's web-browser. However, any website may submit GET and POST requests to other websites, to which the browser will automatically add the session token if it is in a cookie. This cross-site request can then be trusted as arriving from the user's browser, but does not validate that its intent was to make this request.

## General Recommendations

Mitigating CSRF requires an additional layer of authentication that is built into the request validation mechanism. This mechanism would attach an additional token that only applies to the given user; this token would be available within the user's web-page, but will not be attached automatically to a request from a different website (e.g. not stored in a cookie). Since the token is not automatically attached to the request, and is not available to the attacker, and is required by the server to process the request, it would be completely impossible for the attacker to fill in a valid cross-site form that contains this token.

Many platforms offer built-in CSRF mitigation functionality which should be used, and perform this type of token management under the hood. Alternatively, use a known or trusted library which adds this functionality.

If implementing CSRF protection is required, this protection should adhere to the following rules:

- \* Any state altering form (Create, Update, Delete operations) should enforce CSRF protection, by adding a CSRF token to every state altering form submission on the client.
  - \* An CSRF token should be generated, and be unique per-user per-session (and, preferably, per request).
  - \* The CSRF token should be inserted into the client side form, and be submitted to the server as part of the form request. For example, it could be a hidden field in an HTML form, or a custom header added by a Javascript request.
  - \* The CSRF token in the request body or custom header must then be verified as belonging to the current user by the server, before a request is authorized and processed as valid.

## Broken\_or\_Risky\_Hashing\_Function (CWE 327)

## What Is The Risk

Using unsecure hashing for cryptographic purposes can apply to one, or both, of the following scenarios: - If the hashing function is not strong enough for computing power, it would be possible to reverse a mathematically irreversible, but insufficiently expensive, hashing algorithm. By simply computing its possible output permutations as a dictionary (a Rainbow table) - it would be possible to reverse a one-way function - If the hashing function itself is broken or cryptographically weak, despite being intended for cryptographic purposes, it may be possible to break validation logic for which hashing is used. For example, collision-prone cryptographic hashes may be vulnerable to exploitation where attackers can forge malicious or tampered data that would fit a trusted hash value that is used as a signature, bypassing validation

## What Can Cause It

The chosen cryptographic hashing function is broken, deprecated or obsolete. If the hashing function is not used for cryptographic purposes, a non-cryptographic hashing function should be used in its stead to reduce unnecessary computational overhead. If a hashing function is used for cryptographic purposes - a cryptographically secure function should be used instead.

## General Recommendations

- Do not use any broken hashing functions, cryptographic or otherwise, such as MD5, SHA1, etc.
  - Avoid, where possible, using legacy algorithms that are not considered "future-proof" with sufficient safety margins, even though they are considered "safe enough" by current standards. This includes functions that rely on broken algorithms, such as bcrypt's reliance on the obsolete Blowfish algorithm.

## Broken\_or\_Risky\_Encryption\_Algorithm (CWE 327)

## What Is The Risk

Using weak or broken encryption algorithms puts data confidentiality and integrity at risk. These algorithms can either be broken or successfully brute-forced to crack encryption, thus allowing retrieval, or tampering, of encrypted data.

## What Can Cause It

The application relies on a broken, weak or untested encryption algorithm.

---

## General Recommendations

- Only use strong, approved cryptographic algorithms, such as AES-512
  - Avoid using old, broken, deprecated or weak algorithms such as DES or Blowfish
  - Consider avoiding encryption algorithms that are not considered future-proof due to increases in computation power, such as AES-128
